

Frontend Assessment — Tip Calculator

Submission Guidelines:

- Working frontend code (any web stack — vanilla HTML/CSS/JS, React, Vue, Svelte, Solid, anything reasonable that runs in a browser)
- A `README.md` with a single command or clear steps to run it locally (and a deployed URL if you have one — Vercel, Netlify, GitHub Pages, your call)
- An `ANSWERS.md` file at the repo root, answering the 5 questions below
- At least one commit history showing progress (not a single dump commit)

The 5 `ANSWERS.md` questions (identical across variants)

1. How to run: Give the exact command(s) or steps to run your project on a fresh machine. If anything needs installing, list it. If you've deployed it, include the URL.
2. Stack & design choices: Why did you pick this frontend stack for this task? Then walk us through 2 specific visual or interaction decisions you made — not "I used blue," but something like "I made the timer take 60% of the viewport because..." or "I picked a grid over a list because..." Point to the part of the app each decision affects.
3. Responsive & accessibility: How does your app behave on a 360px-wide phone vs. a 1440px laptop? What's one accessibility consideration you handled (keyboard nav, focus states, color contrast, screen reader labels, anything specific)? What's one you knowingly skipped and why?
4. AI usage: List every place you used AI (which tool, what you asked, what it gave you). For at least one of these, describe something you changed about the AI output and why. Be specific — "I tweaked the styling" is not an answer; "the AI gave me a grid with fixed columns and I switched it to `auto-fit minmax` so the cards reflow on narrow screens" is.

Honest gap: What's one thing in your submission that isn't polished enough, and what would you do to fix it with another day?

Tip calculator / bill splitter

Build a single-screen tip calculator and bill splitter as a web app. The user enters a bill amount, a tip percentage, and a number of people, and the app shows what each person owes — updating live as they type, with no "calculate" button.

Inputs: a bill amount (pick a currency — Rs, \$, whatever — and label it clearly); a tip percentage with preset buttons like 10% / 15% / 20% plus a custom % input, with the currently active preset visually distinct; and a number of people. The live output panel should show at minimum the total tip amount, the grand total (bill + tip), and the per-person share of bill + tip.

Validation must be inline — visible error messages near the offending field, not `window.alert`, not browser-default tooltips. Bill must be a positive number. Tip % must be ≥ 0 and within a sensible upper bound you pick. Number of people must be a positive integer ≥ 1 . Include a reset button that returns the app to a clean state.

Pick a rounding policy and defend it in ANSWERS.md — when the per-person amount has more than 2 decimal places, what happens? Round to nearest, round up so the group never underpays, distribute the remainder across people, something else? Your call.

Build it with whatever frontend stack you're best at. We will open your app in a browser and try realistic scenarios — including some designed to break it (zero people, negative bills, pasted garbage text, very large numbers).

Where you'll be judged hardest is on how the app responds to input. Numbers should update smoothly as the user types. Errors should appear and disappear gracefully, not flicker. The keyboard experience matters — tab order, Enter behavior, mobile keyboard not covering the result. Spend the time you save by not having persistence on getting the interaction right.
